

Title

Baseline characteristics of adults enrolled in an evaluation of home blood pressure monitoring: evidence from participating centres

Abstract

This baseline report describes 117 adults enrolled to assess home blood pressure monitoring for hypertension. Participants were recruited within a pragmatic network of hospital and community providers; baseline severity, medication use, functional status, and social factors were recorded before treatment allocation. The cohort was broadly representative of the intended clinical population, although referral patterns may affect external validity. The analysis also considered differences between hospital and community delivery settings. This report is from a parallel-group randomized controlled trial comparing Control: placebo education vs Intervention: CBT + strength and balance exercise.
