

Title

Healthcare utilization during home blood pressure monitoring for hypertension: findings from routine clinical practice

Abstract

A within-trial economic evaluation estimated healthcare use and costs associated with home blood pressure monitoring for hypertension. Resource use, service contacts, medication changes, and quality-adjusted survival were compared with standard care. Results were sensitive to assumptions about intervention delivery and longer-term maintenance. Cost estimates were presented from the healthcare-system perspective and in sensitivity analyses from a wider societal perspective. This report is from a parallel-group randomized controlled trial comparing Control: placebo education vs Intervention: CBT + strength and balance exercise.
