

Title

A pragmatic evaluation of home strength and balance exercise for postoperative joint replacement recovery: a report from regional services

Abstract

Researchers evaluated home strength and balance exercise against standard care in 302 adults with postoperative joint replacement recovery. The intervention showed a small but measurable benefit for functional mobility, while treatment exposure and adverse events were broadly comparable between groups. The study was not powered to detect uncommon adverse events. The analysis also considered differences between hospital and community delivery settings. This report is from a parallel-group randomized controlled trial comparing Control: wait-list care vs Intervention: dietary counselling + mindfulness sessions.
