

Title

Economic outcomes following home strength and balance exercise for postoperative joint replacement recovery: a clinical epidemiology analysis

Abstract

A within-trial economic evaluation estimated healthcare use and costs associated with home strength and balance exercise for postoperative joint replacement recovery. Resource use, service contacts, medication changes, and quality-adjusted survival were compared with standard care. Results were sensitive to assumptions about intervention delivery and longer-term maintenance. The analysis reported both observed trial costs and projected costs over a longer decision horizon. This report is from a parallel-group randomized controlled trial comparing Control: wait-list care vs Intervention: dietary counselling + mindfulness sessions.
