

Title

A pragmatic evaluation of home strength and balance exercise for postoperative joint replacement recovery: an analysis of resource use

Abstract

The trial team compared home strength and balance exercise against standard care in 302 adults with postoperative joint replacement recovery. The primary analysis indicated a modest improvement for functional mobility, while treatment exposure and adverse events were broadly comparable between groups. Interpretation is limited by attrition and the pragmatic delivery setting. The analysis was designed to reflect the decisions faced by clinicians in routine practice. This report is from a parallel-group randomized controlled trial comparing Control: wait-list care vs Intervention: dietary counselling + mindfulness sessions.
