

Title

Outcomes following personalised dietary counselling for hypertension: a study of care access and outcomes

Abstract

A multicentre investigation examined personalised dietary counselling against standard care in 339 adults with hypertension. The observed difference was clinically interpretable for systolic blood pressure, while treatment exposure and adverse events were broadly comparable between groups. The findings should be considered alongside short follow-up and incomplete adherence data. Differences in adherence were more pronounced among participants recruited through community services. This report is from a parallel-group randomized controlled trial comparing Control: routine care vs Intervention: mindfulness sessions + educational material.
