

Title

Cost and resource implications of personalised dietary counselling for hypertension: a report on clinical decision-making

Abstract

A within-trial economic evaluation estimated healthcare use and costs associated with personalised dietary counselling for hypertension. Resource use, service contacts, medication changes, and quality-adjusted survival were compared with standard care. Results were sensitive to assumptions about intervention delivery and longer-term maintenance. Results depended most strongly on the assumed rate of continued service use after the study period. This report is from a parallel-group randomized controlled trial comparing Control: routine care vs Intervention: mindfulness sessions + educational material.
