

Title

A pragmatic evaluation of brief sleep restriction therapy for insomnia in older adults: a pragmatic service evaluation

Abstract

Investigators explored brief sleep restriction therapy against standard care in 376 adults with insomnia in older adults. The observed difference was clinically interpretable for sleep efficiency, while treatment exposure and adverse events were broadly comparable between groups. Generalisability may be reduced because participating sites had established research infrastructure. The findings are intended to inform evidence synthesis rather than replace confirmatory trials. This report is from a parallel-group randomized controlled trial comparing Control: usual care vs Intervention: CBT + educational material.
