

Title

Primary results from home pulmonary rehabilitation for chronic obstructive pulmonary disease: a multisite effectiveness study

Abstract

Investigators explored home pulmonary rehabilitation against standard care in 487 adults with chronic obstructive pulmonary disease. Results were consistent with the prespecified hypothesis for exercise tolerance, while treatment exposure and adverse events were broadly comparable between groups. Interpretation is limited by attrition and the pragmatic delivery setting. The analysis was designed to reflect the decisions faced by clinicians in routine practice. This report is from a parallel-group randomized controlled trial comparing Control: routine care vs Intervention: inhaled anti-inflammatory therapy + pharmacist medication review.
