

Title

Adverse events and treatment exposure during structured medication review for heart failure with preserved ejection fraction: a real-world assessment of delivery

Abstract

Safety data from the evaluation of structured medication review for heart failure with preserved ejection fraction were reviewed across 141 participants. Most events were mild or unrelated to treatment; serious events were uncommon and balanced between groups. Exposure, discontinuation, and protocol deviations are reported to support interpretation of the clinical outcome findings. The study team documented variation in delivery intensity across participating sites. This report is from a parallel-group randomized controlled trial comparing Control: placebo education vs Intervention: telemonitoring coaching + dietary counselling.
