

Title

Treatment effects of home strength and balance exercise for postoperative joint replacement recovery: a clinical epidemiology analysis

Abstract

Researchers evaluated home strength and balance exercise against standard care in 215 adults with postoperative joint replacement recovery. The observed difference was clinically interpretable for functional mobility, while treatment exposure and adverse events were broadly comparable between groups. The study was not powered to detect uncommon adverse events. The findings are intended to inform evidence synthesis rather than replace confirmatory trials. This report is from a parallel-group randomized controlled trial comparing Control: routine care vs Intervention: mindfulness sessions + educational material.
