

## Title

Who benefits from home strength and balance exercise? A subgroup analysis in postoperative joint replacement recovery: a service-user experience report, report 50

## Abstract

This analysis explored heterogeneity of response to home strength and balance exercise in adults with postoperative joint replacement recovery. Improvement in functional mobility was observed across several prespecified strata, with the largest estimates among participants with greater baseline impairment. The findings are exploratory and require confirmation in independent cohorts. Recruitment pathways and treatment fidelity were examined to support interpretation of the estimates. This report is from a parallel-group randomized controlled trial comparing Control: routine care vs Intervention: mindfulness sessions + educational material.
