

Title

A pragmatic evaluation of home strength and balance exercise for postoperative joint replacement recovery: a longitudinal safety analysis

Abstract

A multicentre investigation examined home strength and balance exercise against standard care in 215 adults with postoperative joint replacement recovery. Between-group estimates favoured the intervention for functional mobility, while treatment exposure and adverse events were broadly comparable between groups. The findings should be considered alongside short follow-up and incomplete adherence data. The report includes a sensitivity analysis using an alternative definition of the primary outcome. This report is from a parallel-group randomized controlled trial comparing Control: routine care vs Intervention: mindfulness sessions + educational material.
