

Title

Comparative effectiveness of home strength and balance exercise for postoperative joint replacement recovery: a study of implementation fidelity

Abstract

This prospective study assessed home strength and balance exercise against standard care in 215 adults with postoperative joint replacement recovery. The observed difference was clinically interpretable for functional mobility, while treatment exposure and adverse events were broadly comparable between groups. The findings should be considered alongside short follow-up and incomplete adherence data. Patient retention varied by site, with the largest losses occurring before the final assessment. This report is from a parallel-group randomized controlled trial comparing Control: routine care vs Intervention: mindfulness sessions + educational material.
