

Title

Budget impact of home strength and balance exercise for postoperative joint replacement recovery: a report on treatment acceptability

Abstract

A within-trial economic evaluation estimated healthcare use and costs associated with home strength and balance exercise for postoperative joint replacement recovery. Resource use, service contacts, medication changes, and quality-adjusted survival were compared with standard care. Results were sensitive to assumptions about intervention delivery and longer-term maintenance. Costs were separated into intervention delivery, primary care, hospital care, and medication use. Site-level differences were retained in the model rather than treated as measurement error. This report is from a parallel-group randomized controlled trial comparing Control: routine care vs Intervention: mindfulness sessions + educational material.
