

Title

Adverse events and treatment exposure during brief sleep restriction therapy for insomnia in older adults: a pragmatic service evaluation

Abstract

Safety data from the evaluation of brief sleep restriction therapy for insomnia in older adults were reviewed across 289 participants. Most events were mild or unrelated to treatment; serious events were uncommon and balanced between groups. Exposure, discontinuation, and protocol deviations are reported to support interpretation of the clinical outcome findings. Results were broadly stable after adjustment for age, baseline severity, and prior treatment. This report is from a parallel-group randomized controlled trial comparing Control: placebo education vs Intervention: CBT + strength and balance exercise.
