

Title

Comparative effectiveness of pacing and energy conservation coaching for post-viral fatigue syndrome: findings from routine clinical practice

Abstract

Investigators explored pacing and energy conservation coaching against standard care in 326 adults with post-viral fatigue syndrome. Between-group estimates favoured the intervention for physical function, while treatment exposure and adverse events were broadly comparable between groups. The study was not powered to detect uncommon adverse events. The report discusses how missing observations may affect interpretation of the final estimates. This report is from a parallel-group randomized controlled trial comparing Control: wait-list care vs Intervention: strength and balance exercise + inhaled anti-inflammatory therapy.
