

Title

A pragmatic evaluation of home blood pressure monitoring for hypertension: a participant-level secondary analysis

Abstract

This prospective study assessed home blood pressure monitoring against standard care in 363 adults with hypertension. The observed difference was clinically interpretable for glycaemic control, while treatment exposure and adverse events were broadly comparable between groups. Generalisability may be reduced because participating sites had established research infrastructure. The analysis also considered differences between hospital and community delivery settings. This report is from a parallel-group randomized controlled trial comparing Control: routine care vs Intervention: inhaled anti-inflammatory therapy + pharmacist medication review.
