

## Title

Comparative effectiveness of home strength and balance exercise for postoperative joint replacement recovery: an outpatient outcomes study

## Abstract

An outpatient research network tested home strength and balance exercise against standard care in 128 adults with postoperative joint replacement recovery. Results were consistent with the prespecified hypothesis for functional mobility, while treatment exposure and adverse events were broadly comparable between groups. Generalisability may be reduced because participating sites had established research infrastructure. The report distinguishes protocol-defined outcomes from exploratory measures collected during follow-up. This report is from a parallel-group randomized controlled trial comparing Control: usual care vs Intervention: CBT + educational material.
