

Title

Efficacy and safety of pacing and energy conservation coaching for post-viral fatigue syndrome: a service-user experience report

Abstract

An outpatient research network tested pacing and energy conservation coaching against standard care in 239 adults with post-viral fatigue syndrome. The primary analysis indicated a modest improvement for physical function, while treatment exposure and adverse events were broadly comparable between groups. The findings should be considered alongside short follow-up and incomplete adherence data. The findings are intended to inform evidence synthesis rather than replace confirmatory trials. This report is from a parallel-group randomized controlled trial comparing Control: routine care vs Intervention: inhaled anti-inflammatory therapy + pharmacist medication review.
