

Title

Implementing pacing and energy conservation coaching in routine care for post-viral fatigue syndrome: a longitudinal safety analysis

Abstract

This implementation report describes delivery of pacing and energy conservation coaching for people with post-viral fatigue syndrome across routine services. Staff training, referral pathways, fidelity, reach, and participant engagement were monitored alongside physical function. Adoption was feasible, although local staffing and infrastructure shaped delivery. The analysis also considered differences between hospital and community delivery settings. This report is from a parallel-group randomized controlled trial comparing Control: routine care vs Intervention: inhaled anti-inflammatory therapy + pharmacist medication review.
