

Title

Treatment effects of pacing and energy conservation coaching for post-viral fatigue syndrome: an analysis of resource use

Abstract

Researchers evaluated pacing and energy conservation coaching against standard care in 239 adults with post-viral fatigue syndrome. Between-group estimates favoured the intervention for physical function, while treatment exposure and adverse events were broadly comparable between groups. The findings should be considered alongside short follow-up and incomplete adherence data. Patient retention varied by site, with the largest losses occurring before the final assessment. This report is from a parallel-group randomized controlled trial comparing Control: routine care vs Intervention: inhaled anti-inflammatory therapy + pharmacist medication review.
