

Title

Who benefits from pacing and energy conservation coaching? A subgroup analysis in post-viral fatigue syndrome: an analysis of longer-term use

Abstract

This analysis explored heterogeneity of response to pacing and energy conservation coaching in adults with post-viral fatigue syndrome. Improvement in physical function was observed across several prespecified strata, with the largest estimates among participants with greater baseline impairment. The findings are exploratory and require confirmation in independent cohorts. The analysis was designed to reflect the decisions faced by clinicians in routine practice. This report is from a parallel-group randomized controlled trial comparing Control: routine care vs Intervention: inhaled anti-inflammatory therapy + pharmacist medication review.
