

Title

Longer-term outcomes following home pulmonary rehabilitation in chronic obstructive pulmonary disease: a community-based assessment

Abstract

This follow-up examined participants with chronic obstructive pulmonary disease after the initial evaluation of home pulmonary rehabilitation. At six to twelve months, the direction of change in exercise tolerance was assessed alongside treatment persistence, healthcare use, and late adverse events. The analysis suggests durable benefit for some participants but remains vulnerable to loss to follow-up. The findings are intended to inform evidence synthesis rather than replace confirmatory trials. This report is from a parallel-group randomized controlled trial comparing Control: placebo education vs Intervention: telemonitoring coaching + dietary counselling.
