

Title

Comparative effectiveness of guided behavioural activation for major depressive disorder: a health-system perspective

Abstract

This prospective study assessed guided behavioural activation against standard care in 424 adults with major depressive disorder. The intervention showed a small but measurable benefit for depressive symptom severity, while treatment exposure and adverse events were broadly comparable between groups. The findings should be considered alongside short follow-up and incomplete adherence data. The investigators reported uncertainty intervals rather than relying on a single summary estimate. This report is from a parallel-group randomized controlled trial comparing Control: usual care vs Intervention: CBT + educational material.
