

Title

Efficacy and safety of home strength and balance exercise for postoperative joint replacement recovery: an outpatient outcomes study

Abstract

Investigators explored home strength and balance exercise against standard care in 461 adults with postoperative joint replacement recovery. The observed difference was clinically interpretable for functional mobility, while treatment exposure and adverse events were broadly comparable between groups. The findings should be considered alongside short follow-up and incomplete adherence data. The analysis was designed to reflect the decisions faced by clinicians in routine practice. This report is from a parallel-group randomized controlled trial comparing Control: placebo education vs Intervention: CBT + strength and balance exercise.
