

Title

Comparative effectiveness of guided behavioural activation for major depressive disorder: a report on clinical decision-making

Abstract

Researchers evaluated guided behavioural activation against standard care in 337 adults with major depressive disorder. The intervention showed a small but measurable benefit for depressive symptom severity, while treatment exposure and adverse events were broadly comparable between groups. The study was not powered to detect uncommon adverse events. Service capacity and local referral practices influenced the observed pattern of care. This report is from a parallel-group randomized controlled trial comparing Control: placebo education vs Intervention: CBT + strength and balance exercise.
