

Title

Adverse events and treatment exposure during guided behavioural activation for major depressive disorder: a multisite patient follow-up

Abstract

Safety data from the evaluation of guided behavioural activation for major depressive disorder were reviewed across 337 participants. Most events were mild or unrelated to treatment; serious events were uncommon and balanced between groups. Exposure, discontinuation, and protocol deviations are reported to support interpretation of the clinical outcome findings. The analysis was designed to reflect the decisions faced by clinicians in routine practice. This report is from a parallel-group randomized controlled trial comparing Control: placebo education vs Intervention: CBT + strength and balance exercise.
