

Title

Comparative effectiveness of personalised dietary counselling for hypertension: a community-based assessment

Abstract

This prospective study assessed personalised dietary counselling against standard care in 411 adults with hypertension. The intervention showed a small but measurable benefit for systolic blood pressure, while treatment exposure and adverse events were broadly comparable between groups. Generalisability may be reduced because participating sites had established research infrastructure. Results were broadly stable after adjustment for age, baseline severity, and prior treatment. This report is from a parallel-group randomized controlled trial comparing Control: routine care vs Intervention: inhaled anti-inflammatory therapy + pharmacist medication review.
