

Title

Efficacy and safety of home strength and balance exercise for postoperative joint replacement recovery: a service-user experience report

Abstract

The trial team compared home strength and balance exercise against standard care in 287 adults with postoperative joint replacement recovery. The observed difference was clinically interpretable for functional mobility, while treatment exposure and adverse events were broadly comparable between groups. Interpretation is limited by attrition and the pragmatic delivery setting. The investigators noted that the observed association should not be interpreted as proof of causation. This report is from a parallel-group randomized controlled trial comparing Control: routine care vs Intervention: inhaled anti-inflammatory therapy + pharmacist medication review.
