

Title

Adverse events and treatment exposure during brief sleep restriction therapy for insomnia in older adults: an analysis of resource use

Abstract

Safety data from the evaluation of brief sleep restriction therapy for insomnia in older adults were reviewed across 361 participants. Most events were mild or unrelated to treatment; serious events were uncommon and balanced between groups. Exposure, discontinuation, and protocol deviations are reported to support interpretation of the clinical outcome findings. The findings are intended to inform evidence synthesis rather than replace confirmatory trials. This report is from a parallel-group randomized controlled trial comparing Control: placebo education vs Intervention: telemonitoring coaching + dietary counselling.
