

Title

Randomized trial of home pulmonary rehabilitation for chronic obstructive pulmonary disease: evidence from participating centres

Abstract

The trial team compared home pulmonary rehabilitation against standard care in 472 adults with chronic obstructive pulmonary disease. Between-group estimates favoured the intervention for exercise tolerance, while treatment exposure and adverse events were broadly comparable between groups. Generalisability may be reduced because participating sites had established research infrastructure. Service capacity and local referral practices influenced the observed pattern of care. This report is from a parallel-group randomized controlled trial comparing Control: usual care vs Intervention: CBT + educational material.
