

Title

Comparative effectiveness of a graded activity programme for chronic low back pain: a participant-level secondary analysis

Abstract

A multicentre investigation examined a graded activity programme against standard care in 89 adults with chronic low back pain. The primary analysis indicated a modest improvement for pain-related function, while treatment exposure and adverse events were broadly comparable between groups. The findings should be considered alongside short follow-up and incomplete adherence data. Differences in adherence were more pronounced among participants recruited through community services. This report is from a parallel-group randomized controlled trial comparing Control: placebo education vs Intervention: CBT + strength and balance exercise.
