

Title

Implementing home strength and balance exercise in routine care for postoperative joint replacement recovery: a multisite effectiveness study

Abstract

This implementation report describes delivery of home strength and balance exercise for people with postoperative joint replacement recovery across routine services. Staff training, referral pathways, fidelity, reach, and participant engagement were monitored alongside functional mobility. Adoption was feasible, although local staffing and infrastructure shaped delivery. The findings are intended to inform evidence synthesis rather than replace confirmatory trials. This report is from a parallel-group randomized controlled trial comparing Control: usual care vs Intervention: pharmacist medication review + telemonitoring coaching.
