

Title

Who benefits from guided behavioural activation? A subgroup analysis in major depressive disorder: an analysis of resource use

Abstract

This analysis explored heterogeneity of response to guided behavioural activation in adults with major depressive disorder. Improvement in depressive symptom severity was observed across several prespecified strata, with the largest estimates among participants with greater baseline impairment. The findings are exploratory and require confirmation in independent cohorts. Results were broadly stable after adjustment for age, baseline severity, and prior treatment. The analysis separated scheduled contacts from unscheduled healthcare use. This report is from a parallel-group randomized controlled trial comparing Control: usual care vs Intervention: pharmacist medication review + telemonitoring coaching.
