

## Title

Adverse events and treatment exposure during brief sleep restriction therapy for insomnia in older adults: findings from routine clinical practice

## Abstract

Safety data from the evaluation of brief sleep restriction therapy for insomnia in older adults were reviewed across 187 participants. Most events were mild or unrelated to treatment; serious events were uncommon and balanced between groups. Exposure, discontinuation, and protocol deviations are reported to support interpretation of the clinical outcome findings. Service capacity and local referral practices influenced the observed pattern of care. This report is from a parallel-group randomized controlled trial comparing Control: routine care vs Intervention: mindfulness sessions + educational material.
