

Title

Implementing pacing and energy conservation coaching in routine care for post-viral fatigue syndrome: a longitudinal cohort analysis

Abstract

This implementation report describes delivery of pacing and energy conservation coaching for people with post-viral fatigue syndrome across routine services. Staff training, referral pathways, fidelity, reach, and participant engagement were monitored alongside physical function. Adoption was feasible, although local staffing and infrastructure shaped delivery. The analysis was designed to reflect the decisions faced by clinicians in routine practice. This report is from a parallel-group randomized controlled trial comparing Control: usual care vs Intervention: CBT + educational material.
