

Title

Implementing a graded activity programme in routine care for chronic low back pain: a patient-centred outcomes report

Abstract

This implementation report describes delivery of a graded activity programme for people with chronic low back pain across routine services. Staff training, referral pathways, fidelity, reach, and participant engagement were monitored alongside pain-related function. Adoption was feasible, although local staffing and infrastructure shaped delivery. Differences in adherence were more pronounced among participants recruited through community services. This report is from a parallel-group randomized controlled trial comparing Control: routine care vs Intervention: inhaled anti-inflammatory therapy + pharmacist medication review.
