

Title

Implementing structured medication review in routine care for heart failure with preserved ejection fraction: a multisite effectiveness study

Abstract

This implementation report describes delivery of structured medication review for people with heart failure with preserved ejection fraction across routine services. Staff training, referral pathways, fidelity, reach, and participant engagement were monitored alongside symptom burden. Adoption was feasible, although local staffing and infrastructure shaped delivery. Results were broadly stable after adjustment for age, baseline severity, and prior treatment. This report is from a parallel-group randomized controlled trial comparing Control: usual care vs Intervention: pharmacist medication review + telemonitoring coaching.
