

Title

Secondary analysis of symptom burden after structured medication review for heart failure with preserved ejection fraction: a health-system perspective

Abstract

A prespecified secondary analysis examined variation in symptom burden after structured medication review among adults with heart failure with preserved ejection fraction. Effects were explored by baseline severity, age, adherence, and recruitment setting. The pattern was directionally consistent with the primary analysis, but subgroup estimates were imprecise. The findings are intended to inform evidence synthesis rather than replace confirmatory trials. This report is from a parallel-group randomized controlled trial comparing Control: usual care vs Intervention: pharmacist medication review + telemonitoring coaching.
