

Title

Outcomes following guided behavioural activation for major depressive disorder: a real-world assessment of delivery

Abstract

Investigators explored guided behavioural activation against standard care in 409 adults with major depressive disorder. The observed difference was clinically interpretable for depressive symptom severity, while treatment exposure and adverse events were broadly comparable between groups. Interpretation is limited by attrition and the pragmatic delivery setting. The report includes a sensitivity analysis using an alternative definition of the primary outcome. This report is from a parallel-group randomized controlled trial comparing Control: placebo education vs Intervention: telemonitoring coaching + dietary counselling.
