

Title

Patient-reported experience after guided behavioural activation for major depressive disorder: an analysis of treatment persistence

Abstract

This report examined patient-reported experience and quality of life after guided behavioural activation for major depressive disorder. Participants described changes in daily activity, confidence, symptom control, and care burden. Improvements in depressive symptom severity were accompanied by variable satisfaction with access and treatment workload. Patient retention varied by site, with the largest losses occurring before the final assessment. This report is from a parallel-group randomized controlled trial comparing Control: placebo education vs Intervention: telemonitoring coaching + dietary counselling.
