

Title

Secondary analysis of depressive symptom severity after guided behavioural activation for major depressive disorder: a clinical epidemiology analysis

Abstract

A prespecified secondary analysis examined variation in depressive symptom severity after guided behavioural activation among adults with major depressive disorder. Effects were explored by baseline severity, age, adherence, and recruitment setting. The pattern was directionally consistent with the primary analysis, but subgroup estimates were imprecise. The investigators reported uncertainty intervals rather than relying on a single summary estimate. This report is from a parallel-group randomized controlled trial comparing Control: placebo education vs Intervention: telemonitoring coaching + dietary counselling.
