

Title

A pragmatic evaluation of home strength and balance exercise for postoperative joint replacement recovery: a service-user experience report

Abstract

A multicentre investigation examined home strength and balance exercise against standard care in 446 adults with postoperative joint replacement recovery. The observed difference was clinically interpretable for functional mobility, while treatment exposure and adverse events were broadly comparable between groups. The study was not powered to detect uncommon adverse events. The analysis was designed to reflect the decisions faced by clinicians in routine practice. This report is from a parallel-group randomized controlled trial comparing Control: wait-list care vs Intervention: dietary counselling + mindfulness sessions.
