

Title

A pragmatic evaluation of personalised dietary counselling for hypertension: a participant-level secondary analysis

Abstract

This prospective study assessed personalised dietary counselling against standard care in 396 adults with hypertension. The intervention showed a small but measurable benefit for systolic blood pressure, while treatment exposure and adverse events were broadly comparable between groups. The study was not powered to detect uncommon adverse events. Service capacity and local referral practices influenced the observed pattern of care. This report is from a parallel-group randomized controlled trial comparing Control: usual care vs Intervention: CBT + educational material.
