

Title

Implementing pacing and energy conservation coaching in routine care for post-viral fatigue syndrome: a health-system perspective

Abstract

This implementation report describes delivery of pacing and energy conservation coaching for people with post-viral fatigue syndrome across routine services. Staff training, referral pathways, fidelity, reach, and participant engagement were monitored alongside physical function. Adoption was feasible, although local staffing and infrastructure shaped delivery. Results were broadly stable after adjustment for age, baseline severity, and prior treatment. The investigators recorded how referral source influenced service use during follow-up. This report is from a parallel-group randomized controlled trial comparing Control: wait-list care vs Intervention: strength and balance exercise + inhaled anti-inflammatory therapy.
