

Title

Comparative effectiveness of a graded activity programme for chronic low back pain: a report on treatment acceptability

Abstract

This prospective study assessed a graded activity programme against standard care in 161 adults with chronic low back pain. Between-group estimates favoured the intervention for pain-related function, while treatment exposure and adverse events were broadly comparable between groups. Generalisability may be reduced because participating sites had established research infrastructure. Differences in adherence were more pronounced among participants recruited through community services. This report is from a parallel-group randomized controlled trial comparing Control: placebo education vs Intervention: telemonitoring coaching + dietary counselling.
