

Title

Comparative effectiveness of personalised dietary counselling for hypertension: evidence from participating centres

Abstract

Researchers evaluated personalised dietary counselling against standard care in 309 adults with hypertension. Results were consistent with the prespecified hypothesis for systolic blood pressure, while treatment exposure and adverse events were broadly comparable between groups. The study was not powered to detect uncommon adverse events. The analysis also considered differences between hospital and community delivery settings. This report is from a parallel-group randomized controlled trial comparing Control: placebo education vs Intervention: CBT + strength and balance exercise.
