

Title

A Prospective Evaluation of Daily Intraocular Pressure Control With Sepetaprost Versus Latanoprost in Ocular Hypertension and Glaucoma: Protocol for a Novel Therapeutic Comparison

Abstract

Patients with elevated intraocular pressure benefit from pharmacologic therapy, yet identifying optimal treatments requires rigorous comparative evidence. This exploratory protocol evaluates whether sepetaprost--a novel prostaglandin analog--provides superior intraocular pressure reduction over a 24-hour period compared to the established agent latanoprost in adults with primary open-angle glaucoma or ocular hypertension. Approximately 35 participants will be randomly assigned to receive either sepetaprost or latanoprost daily for 12 weeks following a screening phase. The primary outcome is mean 24-hour intraocular pressure measured at the conclusion of treatment. Secondary evaluations include safety assessments, adverse event profiles, and measurements at discrete time points throughout the day and night. This study aims to determine whether the novel formulation offers clinically meaningful advantages in intraocular pressure control.
