

Title

Community perspectives on spatial repellent adoption and integration with conventional malaria control

Abstract

Qualitative evaluation of household acceptance of spatial repellent technology was conducted alongside efficacy assessments. Thirty households were systematically interviewed at 1 week and 2 months post-installation. Early responses were predominantly positive, with most respondents reporting perceived reduction in mosquito nuisance and activity. Key themes included appreciation for continuous protective coverage independent of sleeping behaviors, contrasting with the situational protection of bed nets. Several households expressed initial concerns about product durability and coverage area, particularly following product replacement. Participants requested longer-acting formulations and methods for treating larger household spaces. Installation ease was generally satisfactory, though some respondents suggested alternative mounting approaches. Comparative feedback indicated spatial repellents complemented rather than replaced bed net use in household prevention strategies. Integration of user feedback regarding product optimization and installation technique could enhance acceptability and long-term adherence in similar settings.
